### CSE 604 Artificial Intelligence

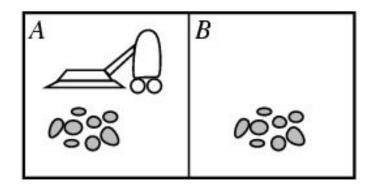

#### Chapter 3: Solving Problems by Searching

Adapted from slides available in Russell & Norvig's textbook webpage

Dr. Ahmedul Kabir

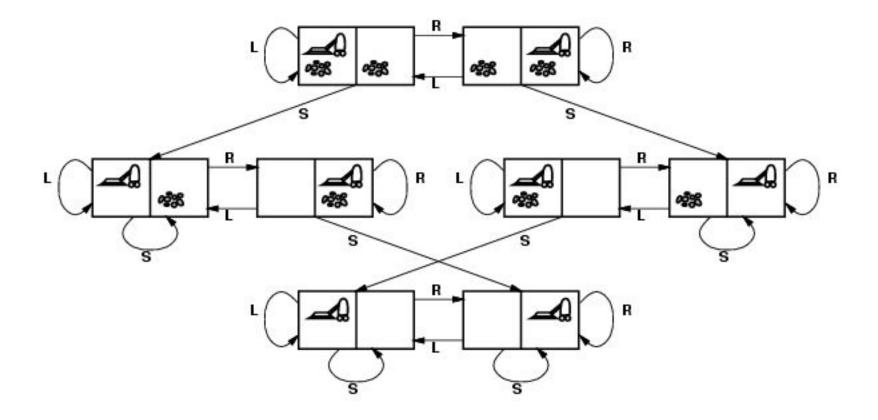

#### Remember the Vacuum-cleaner world?

•Percepts: location and contents, e.g., [A, Dirty]

•Actions: Left, Right, Suck

# Vacuum world state space graph

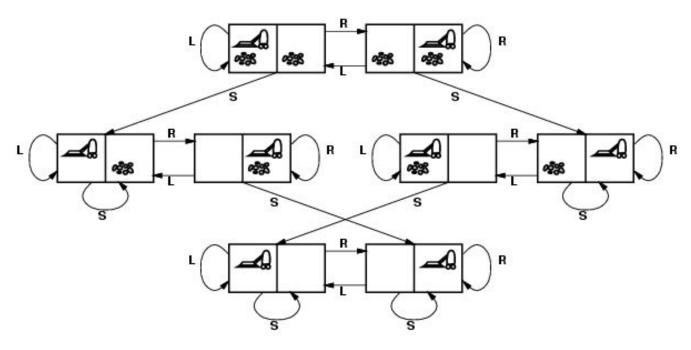

**State space**: Set of all reachable states. In state space graph, nodes/vertices = states, links/edges = actions

#### Formulation of a Problem

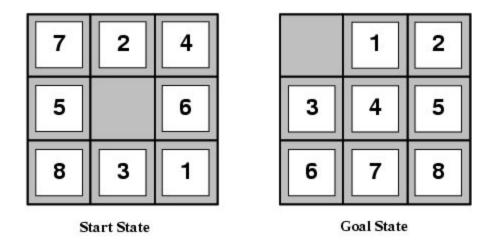

- •A Problem is defined by the following items:
  - Set of states the agent can be in, with a designated initial state
  - Set of actions available to the agent
  - Transition model describing what each action does (maps a <state, action> pair to a state)
  - Goal test which determines if a given state is a goal state
  - A path cost function that assigns a numeric cost to each path

# Vacuum world state space graph

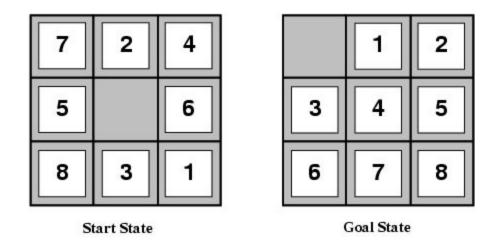

- states? binary dirt and robot location. Any state can be initial state
- <u>actions?</u> Left, Right, Suck
- Transition model? As seen in the state space graph
- goal test? no dirt at all locations
- path cost? 1 per action

## Example: The 8-puzzle

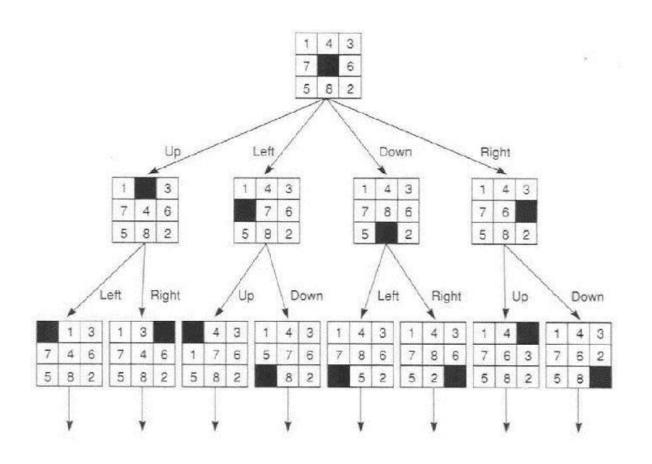

- •states?
- •actions?
- •goal test?
- •path cost?

## Example: The 8-puzzle

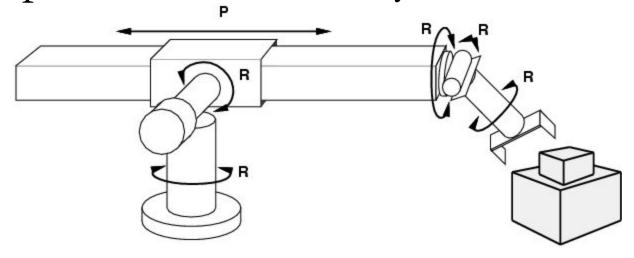

- •states? locations of tiles
- •actions? move blank left, right, up, down
- •goal test? = goal state (given)
- •path cost? 1 per move

## Example: The 8-puzzle

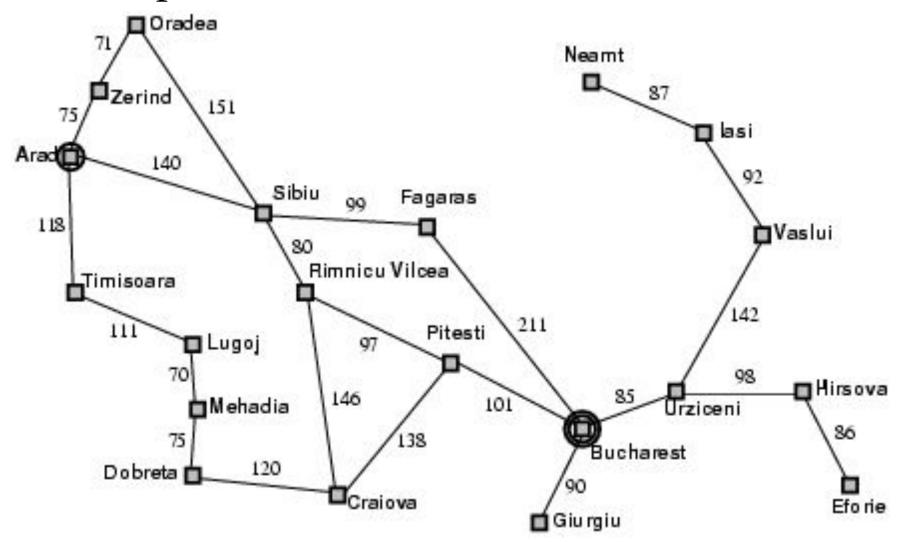

Partial state space graph

#### Example: robotic assembly

- •states?: real-valued coordinates of robot joint angles parts of the object to be assembled
- •actions?: continuous motions of robot joints
- •goal test?: complete assembly
- •path cost?: time to execute

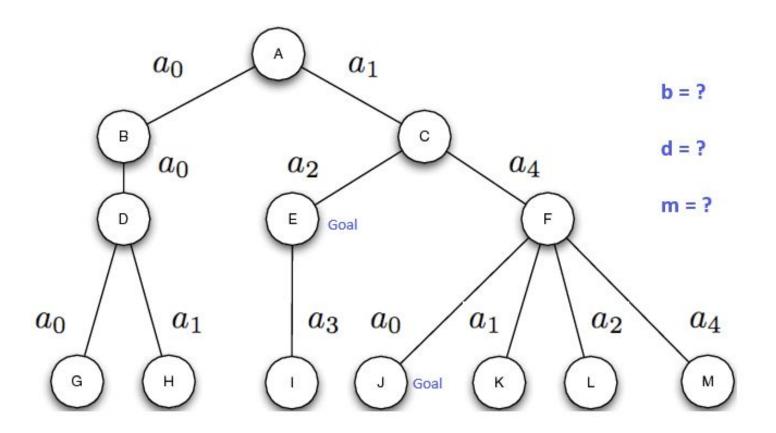

### Example: Romania

#### Search strategies

- A search strategy is defined by picking the order of node expansion
- •Strategies are evaluated along the following dimensions:
  - completeness: does it always find a solution if one exists?
  - time complexity: number of nodes generated
  - space complexity: maximum number of nodes in memory
  - optimality: does it always find a least-cost solution?
- •Time and space complexity are measured in terms of
  - b: maximum branching factor of the search tree
  - d: depth of the least-cost solution
  - *m*: maximum depth of the state space (may be  $\infty$ )

#### Find b, d, m for this tree

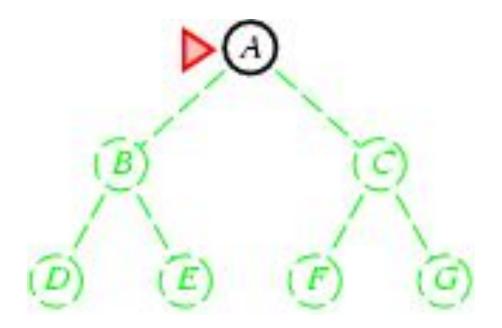

## Uninformed search strategies

- •Uninformed search strategies use only the information available in the problem definition
  - Breadth-first search
  - Uniform-cost search
  - Depth-first search
  - Depth-limited search
  - Iterative deepening search

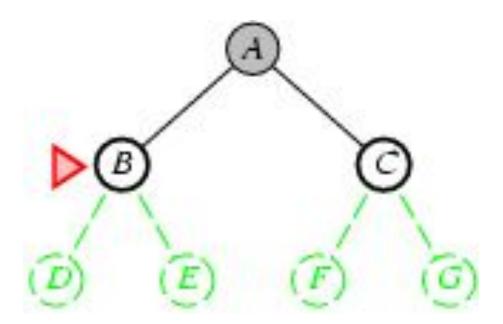

### Basic concept

- Frontier (or fringe): The set of all leaf nodes available for expansion at any given point
- •The basics of each algorithm:
  - Start from initial node
  - Expand adjacent nodes and put them in the frontier
  - Choose the next node from the frontier for expansion
  - Repeat until goal is found, or some ending criteria is met
- •The algorithms differ in the way they choose the next node from the frontier

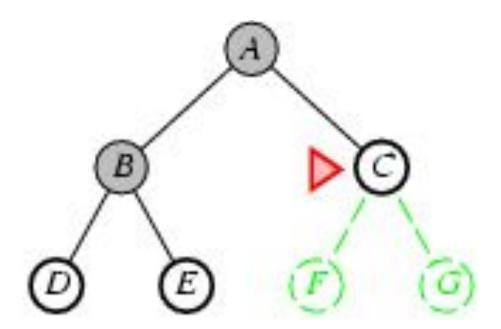

- •Expand shallowest unexpanded node
- •Implementation:
  - frontier is a FIFO queue, i.e., new successors go at end

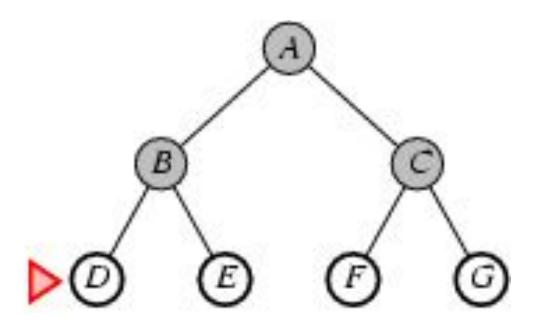

- •Expand shallowest unexpanded node
- •Implementation:
  - frontier is a FIFO queue, i.e., new successors go at end

- •Expand shallowest unexpanded node
- •Implementation:
  - frontier is a FIFO queue, i.e., new successors go at end

- •Expand shallowest unexpanded node
- •Implementation:
  - frontier is a FIFO queue, i.e., new successors go at end

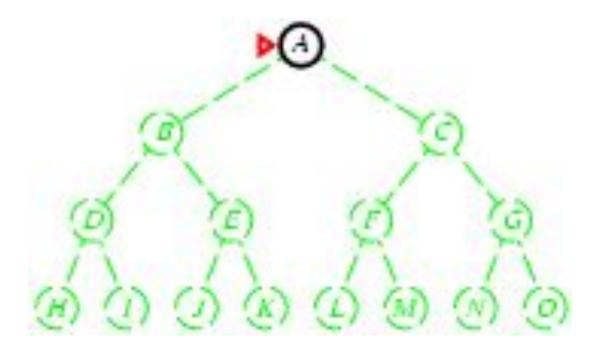

# Properties of breadth-first search

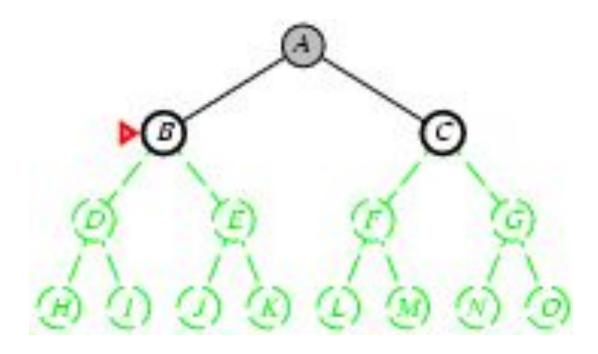

•<u>Complete?</u> Yes (if b is finite)

- •<u>Time?</u>  $1+b+b^2+b^3+...+b^d = O(b^d)$
- •Space?  $O(b^d)$  (keeps every node in memory)
- •<u>Optimal?</u> Yes (if cost = 1 per step)
- •Space is the bigger problem (more than time)

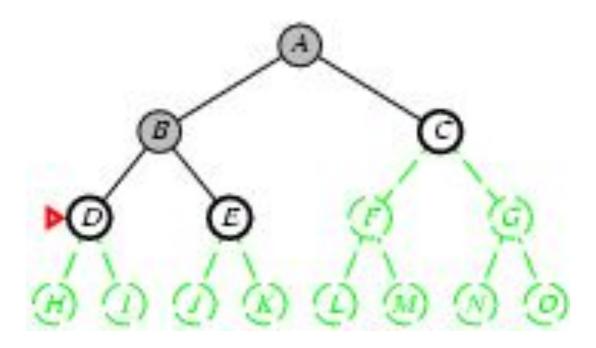

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

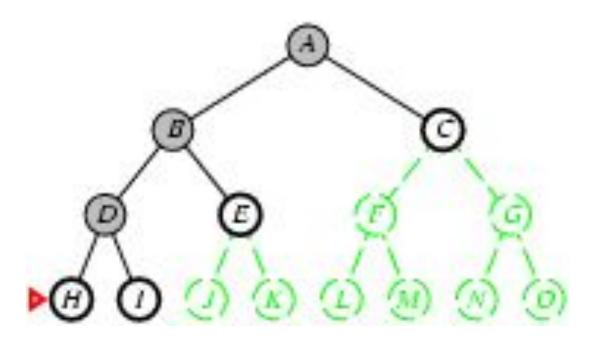

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

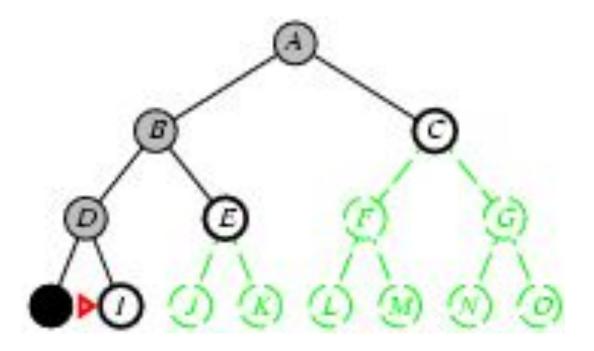

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

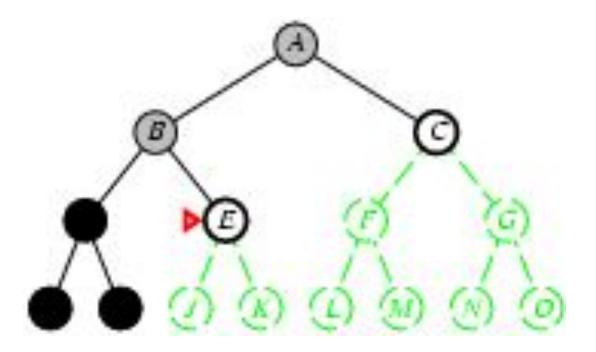

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

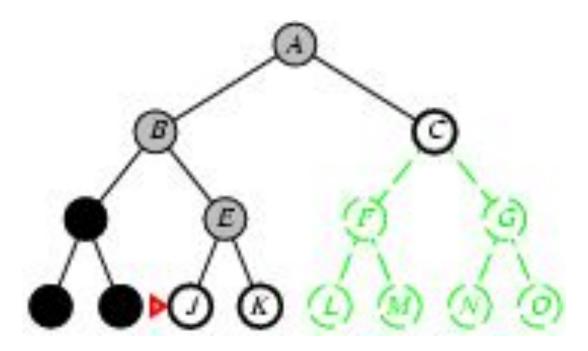

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

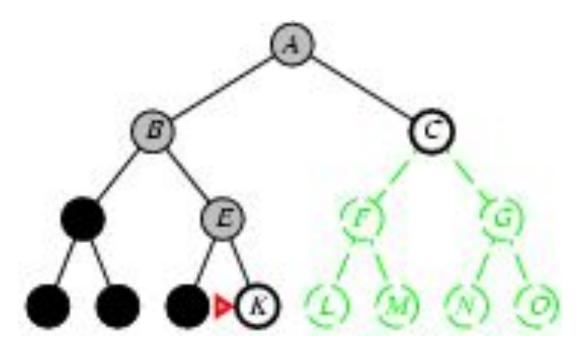

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

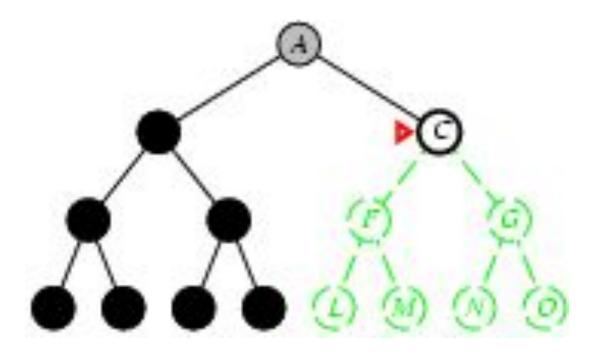

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

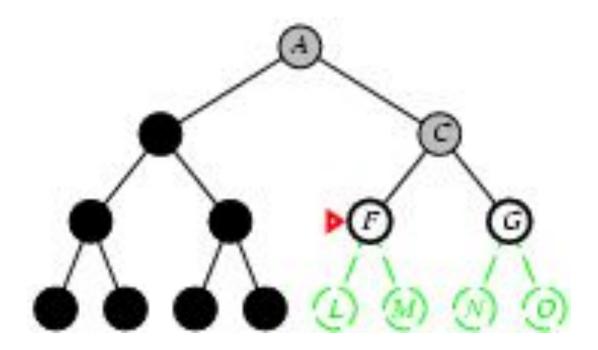

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

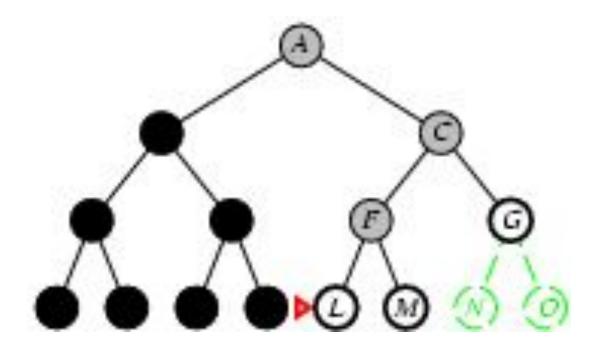

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

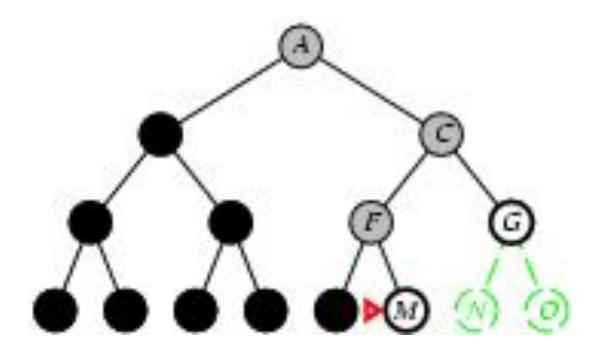

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

- •Expand deepest unexpanded node
- •Implementation:
  - frontier = LIFO stack, i.e., put successors at front

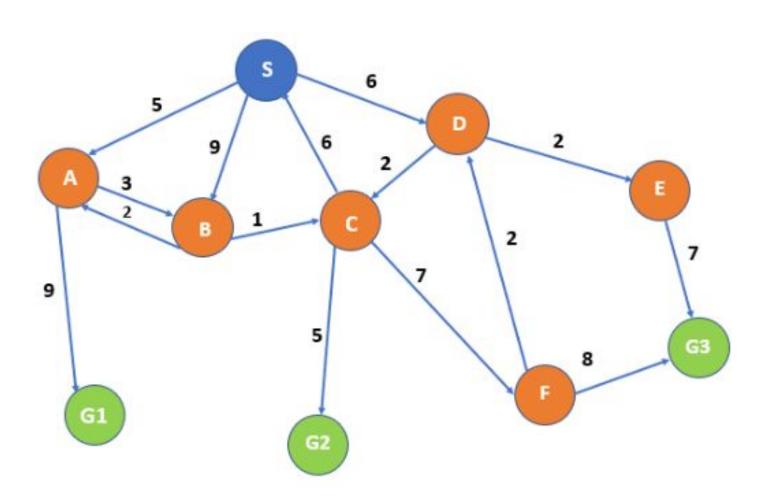

# Properties of depth-first search

- •Complete? No: fails in infinite-depth spaces, spaces with loops
  - Modify to avoid repeated states along path complete in finite spaces
- •<u>Time?</u>  $O(b^m)$ : terrible if m is much larger than d
  - but if solutions are dense, may be much faster than breadth-first
- •Space? O(bm), i.e., linear space!
- •Optimal? No

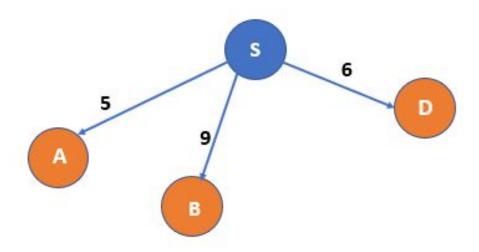

#### Uniform-cost search

- •Expand least-cost unexpanded node
- •Implementation:
  - *frontier* = queue ordered by path cost
- Equivalent to breadth-first if step costs all equal
- Complete? Yes, if step cost  $\geq \varepsilon$
- •<u>Time?</u> # of nodes with  $g \le \cos t$  of optimal solution,  $O(b^{ceiling(C^*/\varepsilon)})$  where  $C^*$  is the cost of the optimal solution
- Space? # of nodes with  $g \le \text{cost of optimal solution}$ ,  $O(b^{\text{ceiling}(C^*/\epsilon)})$
- Optimal? Yes nodes expanded in increasing order of g(n)

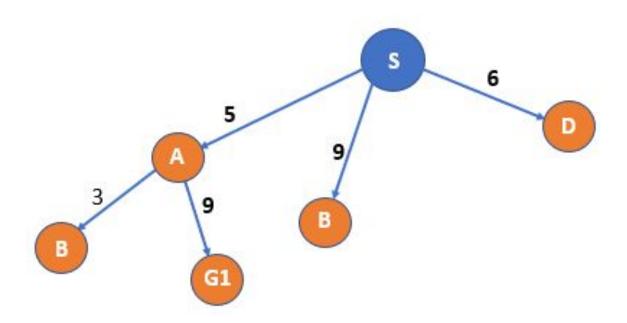

### In-class Example: Uniform Cost Search

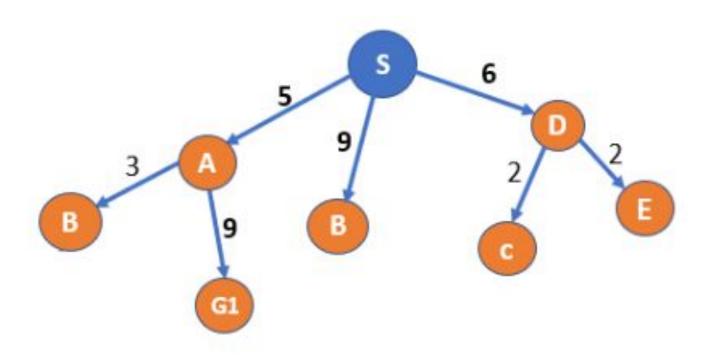

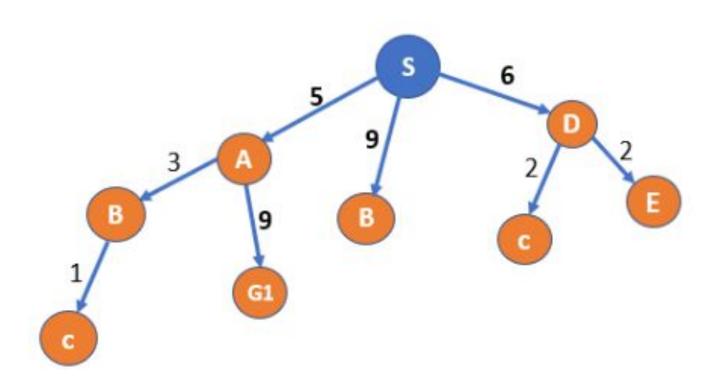

# Uniform Cost Search example

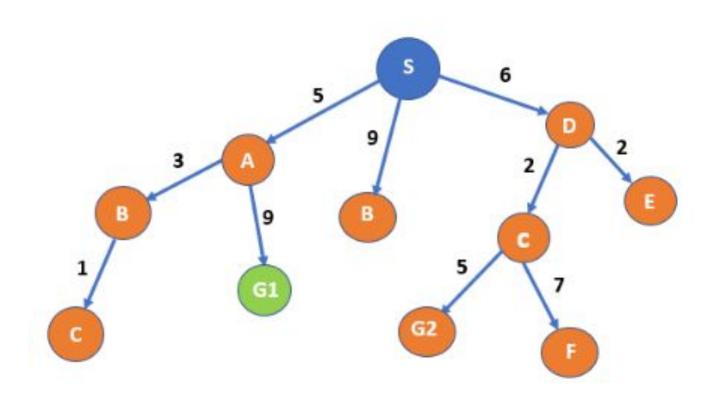

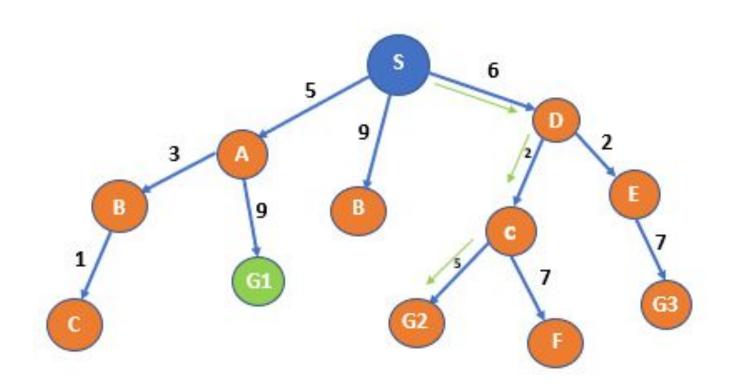

# Uniform Cost Search example

#### Depth-limited search

= depth-first search with depth limit *l*, i.e., nodes at depth *l* have no successors

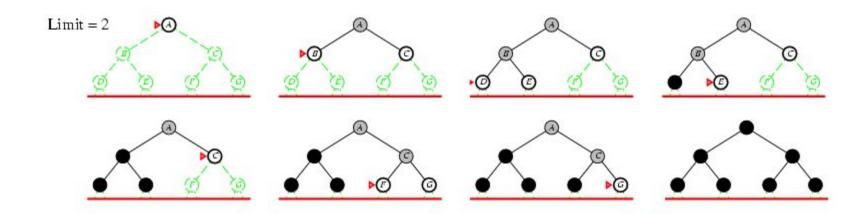

- •Complete? No
- •<u>Time?</u>  $O(b^l)$
- •Space? O(bl)
- •Optimal? No

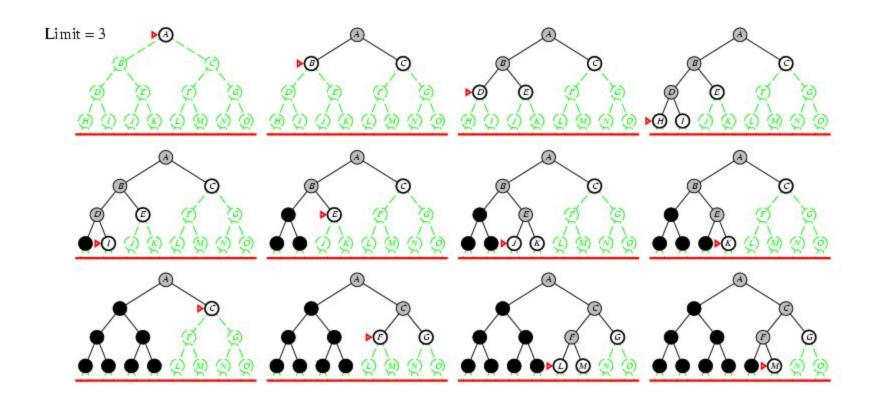

= depth-limited search on repeat!Limit / is increased at each iteration until goal is found

```
function ITERATIVE-DEEPENING-SEARCH( problem) returns a solution, or failure inputs: problem, a problem for depth \leftarrow 0 to \infty do result \leftarrow \text{DEPTH-Limited-Search}(problem, depth) if result \neq \text{cutoff then return } result
```

#### Properties of iterative deepening search

• Complete? Yes

• Time? 
$$(d+1)b^0 + db^1 + (d-1)b^2 + \dots + b^d = O(b^d)$$

•Space? O(bd)

• Optimal? Yes, if step cost = 1

## Summary of algorithms

Criterion	Breadth-	Uniform-	Depth-	Depth-	Iterative
	First	Cost	First	Limited	Deepening
Complete? Time Space Optimal?	$\operatorname{Yes}^a O(b^d) \\ O(b^d) \\ \operatorname{Yes}^c$	$\operatorname{Yes}^{a,b}$ $O(b^{1+\lfloor C^*/\epsilon \rfloor})$ $O(b^{1+\lfloor C^*/\epsilon \rfloor})$ Yes	$egin{array}{c} \operatorname{No} \ O(b^m) \ O(bm) \ \operatorname{No} \end{array}$	No $O(b^\ell)$ $O(b\ell)$ No	$Yes^a$ $O(b^d)$ $O(bd)$ $Yes^c$
